BIOLOGICAL EVALUATION

Western Spruce Budworm Infestation in Southeast Idaho and Northwest Wyoming 1978 1/

INTRODUCTION

For more than two decades the western spruce budworm, Choristoneura occidentalis Free., has been epidemic in mixed conifer stands in portions of southeastern Idaho and northwestern Wyoming (Figure 1). During the last decade, defoliation recorded during the annual detection survey has averaged approximately 104,000 acres. The largest amount of visible damage, amounting to 346,800 acres, was recorded in 1978 (Table 1). The most persistent and widespread outbreaks have occurred on the Bridger-Teton National Forest while the Targhee National Forest has experienced several major fluctuations. Major infestations on the Caribou National Forest have been less frequent and until this year the average yearly recorded defoliation amounted to less than 6,000 acres.

During 1978 changes in the extent and intensity of budworm defoliation occurred throughout the outbreak area. On the Targhee National Forest, approximately 47,000 acres of new infestation occurred in stands located between Teton Pass and Packsaddle Creek to the northwest.

On the Caribou National Forest, new defoliation was recorded on 38,000 acres. New infestations, recorded for the first time in the Grand Teton National Park, occur in several stands along a major travel route through the Park. In addition, the long-standing infestations on the Targhee and Bridger-Teton expanded into uninhabited stands. Distinct from this expansion in area, the Targhee and Bridger-Teton infestations also significantly increased in defoliation intensity.

In addition to the annual egg mass survey conducted to provide a defoliation prediction for the 1979 season, impact data was collected from 18 selected stands. Data included standard tree and stand measurements, radial growth, top kill, and current defoliation. The data were collected and analyzed according to a procedure developed by Region 1 as part of the Canada/U.S. Spruce Budworm Program.

TECHNICAL INFORMATION

INSECT: Western spruce budworm, Choristoneura occidentalis Free.

HOST TREES: Douglas-fir, Pseudotsuga menziesii (Mirb.)

1/ By Lawrence E. Stipe, Ogden Field Office, Forest Insect and Disease Management, U. S. Forest Service, Ogden, Utah.

In addition, increment cores and tree height were collected from the first five host and nonhost trees on each variable plot.

Branch samples were collected as part of a West-wide program designed to improve egg mass sampling as a predictive tool. These data are included to give an estimate of the future trend of these infestations and the level of tree damage expected. Samples were taken from permanent three-tree clusters that had been previously established in areas with budworm defoliation. These samples, consisting of two 70-cm branches, were cut from mid crown position on opposite sides of each of the three trees (six branches per cluster). These branches were individually labeled, bagged and shipped to the Forest Insect and Disease laboratory in Ogden, Utah. Each branch was carefully examined and all egg masses were removed and tallied by cluster.

RESULTS AND DISCUSSION

TARGHEE NATIONAL FOREST

The original green stand (live trees before the infestation) for the ten stands examined on the Targhee National Forest averaged 328 trees per acre (Table 2). The species composition includes Douglas-fir (71 percent), subalpine fir (18 percent), Engelmann spruce (3 percent) and lodgepole pine-aspen (8 percent). Approximately 99 percent or 299 of the 303 host trees per acre have been damaged to some extent by the budworm. Defoliation, top kill and mortality were heaviest in the understory. Nearly 36 trees per acre of the Douglas-fir understory were killed while only 3 trees per acre were killed in the 5 to 11.9-inch dbh category and no mortality occurred in the trees above 12 inches dbh. These data suggest that tree damage and mortality increase as tree size decreases. Individual stand data are summarized in Tables 3 through 12.

The actual mean periodic annual increment for trees 5 inches dbh and larger for the ten stands on the Targhee National Forest was 38.01 (cu.ft. vol/acre/yr.) for Douglas-fir, 7.6 for subalpine fir and 3.7 for spruce (Table 22). For the four years of this infestation, these figures represent an annual growth loss of 7.8 percent, 16.0 percent and 13.8 percent, respectively. Stands with high egg mass counts were generally those with the largest percentage of growth reduction. These data, not correlated by way of a rigid analyses, support the rationale that growth loss is heaviest in areas where populations and subsequent defoliation is the highest. This same relationship also holds true with degrees of defoliation and the amount of top kill observed.

Egg mass data indicate that defoliation will be, at least, moderate to heavy in most stands in the West and East Divisions on the Targhee.

No trend samples were collected during 1977 in the South Division. Since much of this infestation area was new in 1978, the populations are expected

CARIBOU NATIONAL FOREST

Egg mass and stand data were not collected on the Caribou due to bad weather and a lack of personnel near the end of last field season. Following two years of no visible defoliation, over 38,000 acres were detected in 1978. Much of this was in stands infested for the first time in many years. Without additional information, the trend and intensity of this infestation in 1979 is unknown. One might speculate it will continue, but fluctuations have been common on the Caribou (Table 1). This is the first time there has been an increase of this magnitude.

SURVEY COSTS SUMMARY

Aerial Survey

Aircraft - Targhee	\$ 4,280.00
- Bridger-Teton (Park)	4,420.00
- Caribou	2,160.00
Observer Salary	1,530.00
Travel and per diem	<u>450.00</u>
	\$12,840.00

Stand Impact Evaluation

Vehicles	\$ 4,550.00
Field Crew Salaries	1,434.00
Equipment	350.00
Travel and per diem	4,290.00
Contributed by YACC	<u>1,996.00</u>
	\$12,620.00

Egg Mass Evaluation

Field Crew Salaries	\$ 4,360.00
Lab Crew Salaries	2,075.00
Travel and per diem	2,110.00
Equipment	350.00
Contributed by YACC (field)	450.00
Contributed by YACC (lab)	<u>580.00</u>
	\$ 9,925.00

TOTAL SURVEY	\$35,385.00
--------------	-------------

RECOMMENDATIONS

1. Forest Insect and Disease personnel should conduct aerial detection and egg mass surveys in all major infestation areas. New egg mass
